MULTIPLE CHOICE

1. Managerial economics can best be defined as the:
   a) analysis of the leadership styles of managers in an organization.
   b) study of economic incentives on consumer behavior and demand.
   c) analysis of the labor market through the behavior of workers and managers.
   d) analysis of major management decisions using economic tools.
   e) study of the strategic interaction between firms in a market.

   ANSWER: d

SHORT ANSWERS

20. Carefully define managerial economics, and explain how it is useful in decision-making.

   ANSWER: Managerial economics is the analysis of major management decisions using the tools of economics. It applies familiar concepts such as demand, cost, market structure, and resource allocation. Managerial economics emphasizes the theory of the firm and employs quantitative analysis in making decisions. Simple models are used to emphasize the most important features of the decision problem.

21. How can the decision making process be structured such that complicated decisions can be analyzed using a common approach?

   ANSWER: The decision making process can be summarized into a basic framework and used in economic analysis. Decision making can be structured into the following six steps:
   (1) Defining the problem: Since decisions are not made in a vacuum, the context of the decision, the problem itself, and the decision maker need to be identified.
   (2) Setting the objectives: The objectives that are set will determine the guiding rule for the decision. For example, if the objective is to maximize profit then the decision that is most likely to lead to profit-maximization will be chosen over a decision that might lead to maximization of market share.
   (3) Exploring the alternatives: All the alternative courses of action need to be listed out and the most feasible one should be chosen.
(4) Predicting the consequences: Although the outcome of a decision cannot be predicted with certainty, predictive models can be used to predict outcomes with a reasonable level of certainty.

(5) Choosing an option: The right choice should be made based on all the previous steps. If the decision is not immediately clear, various methods like marginal analysis, decision trees, game theory, benefit-cost analysis, and linear programming can be used to clarify the analysis.

(6) Using sensitivity analysis: Once a choice is made, the sensitivity analysis method can be used to check if the decision will be drastically affected by any changes in any of the key assumptions.

22. What are the two difficulties that may make profit maximization an ambiguous guide to decision making? Explain.

ANSWER: The timing of benefits and costs and the presence of risk and uncertainty are the two difficulties that complicate the objective of profit maximization. Generally speaking, many decisions involve making costly investments “up front” in return for benefits or profits in the future. This requires the decision-maker to develop comparable measures of present and future monetary values. Uncertainty underscores the fact that some outcomes are not known with complete confidence. Costs may be far larger than expected, benefits far smaller, and delays in completion may diminish profits. The manager’s task is to foresee the range of possible outcomes and to estimate the likelihood of different consequences.

DIFFICULTY LEVEL: Easy
PAGE: 8

23. One of the major steps in decision-making is to explore the alternatives. Do most managerial decisions have a few, limited number of options? Explain. Illustrate your answer with an appropriate example.

ANSWER: Most decisions have several (often many) competing options. Even when the choices are limited, there are often more alternatives than first meet the eye. For example, Disney would not only have to decide whether to build a new theme park, but it would also have to choose the location, and the scale of operation. In addition, subsequent decisions will involve advertising and pricing strategies. Many managerial decisions involve more than a once-for-all choice from a set of options. Instead, managers face a sequence of decisions. For instance, whether a firm should attempt to develop a new product and if all goes well, when and how should it launch and promote the product. The firm will also have
to decide how it should price the product and gear up capacity to supply the expected sales
at its chosen price.

24. Carefully define the term "model" and explain how models are used in managerial
economics.

ANSWER: A model is a simplified description of a process, relationship, or other
phenomenon. The two main types of models are deterministic and probabilistic. Models
select key features for analysis (and, therefore, they deliberately ignore less important
features). Models are useful to managers because they show how the various options that a
manager faces translate into outcomes. Models usually help in explaining past outcomes or
in predicting future outcomes.

DIFFICULTY LEVEL: Easy
PAGE: 10-11

25. Carefully define probabilistic and deterministic models, and explain how they differ.

ANSWER: Deterministic models are predictive models in which the outcome of a decision
is certain (or close enough that it doesn’t matter). In probabilistic models, there is no one
certain outcome but, rather, many possible outcomes with a probability attached to each.

26. Value maximization is the main objective of top management. Briefly describe the
alternative objectives.

ANSWER: The three most important alternatives are: satisficing behavior, sales
maximization, and pursuing the firm’s social responsibilities to all stakeholders. Satisficing
behavior posits that firms will sometimes strive for second-best, or an acceptable level of
performance as against the highest level of maximization. Sales targets may closely be
linked to managers’ compensation and so firms may also strive to maximize sales subject to
a certain level of profit. Firms that pursue social responsibility as their objective would aim
to satisfy not only customers and investors but also society, the environment, and other
stakeholders. All these objectives may be pursued at the expense of profits.

27. Ecotopia is a developing country that is facing a growing need for energy to power its industries and fuel its development. The Ecotopian government's proposal to set up a nuclear energy plant has drawn widespread protests from environmental activists across the country. Since this is an issue that affects a large number of people, how would one weight the benefits and costs to make a decision that is best for the society as a whole?

ANSWER: Setting up a nuclear plant in order to satisfy civilian energy needs affects the welfare of the society in general. In such a situation, since there are gains and losses for different groups of people, benefit-cost analysis should be used. Benefit-cost analysis weighs the total benefits and total costs of a decision (irrespective of who these benefits and losses accrue to). When setting up a nuclear plant, the benefits and costs need to be assigned a monetary value. If the value of the benefits is higher than the value of the costs, then the project should be undertaken. One of the possible benefits from nuclear energy is that Ecotopia can reduce its dependence on fossil fuels. Nuclear energy generation also does not emit greenhouse gases. The costs that will have to be considered will involve the return on the high investment required to set up a new plant, and the safety of the nuclear plant, and the costs of using and disposing nuclear fuel. All these benefits and costs should be converted into a common measurable unit, usually dollars, and then compared.

28. How does decision making in the private, for-profit sector differ from decision making in the public sector?

ANSWER: In the private sector, managers seek maximum value for the firm. Managers focus primarily on the effects of a decision on the firm's profits. With an eye on profit, managers will not generally take into account the impacts (benefits and costs) on other parties. In the public sector, decisions are guided by benefit-cost analysis (not simply profit analysis). The benefits and costs to all affected parties (not just the program's revenues and costs) are evaluated and totaled in order to make a sound decision.

ESSAYS
29. Amanda is a troubleshooter for a major manufacturing firm. It seems that a particular facility has experienced problems with quality for several years. In addition, there have been some major problems with the facility's labor union. A bitter strike, lasting six months, occurred prior to signing the current contract. Past management teams have visited and inspected the site but have been unable to achieve change, despite detailed study and recommendations. Recently, sales of the facility's product line have declined in the face of increased import competition from an East Asian country, and this is unlikely to change in the near future. Currently, the Board is considering two new courses of action. One is retooling the facility to manufacture a new line of products. This would involve capital costs of several millions of dollars. It would also mean that there would be no production from the facility while retooling and retraining takes place. The second option is closing down the facility. This would involve costs in the form of termination benefits, as well as funding some pension benefits of senior employees. There appear to be no buyers for the plant, and it would likely remain idle for some time, while continuing to be a tax drain on the company. How would Amanda use the steps of decision-making and the concept of value maximization to recommend a course of action to the Board? Explain.

ANSWER: Management finds itself on the horns of a dilemma since it appears that any course of action – continuing current production, retooling, or closing the plant – will involve losses. Nonetheless, the tools of managerial economics still apply. Here, the firm seeks the course of action that minimizes its losses (If losses are minimized, then the value of the firm is maintained as far as possible). Thus, management must carefully estimate and compare the relative costs of its options.

30. Carefully define sensitivity analysis, and provide three examples of how a manager might use it.

ANSWER: Sensitivity analysis considers how an optimal decision would change if key economic facts or conditions were altered. Some examples of how to use it include:
(1) predicting sales under different macroeconomic conditions (growth or recession)
(2) the effects of escalating oil prices on energy costs
(3) the effect on the sales of a product if a competitor cuts prices
In each case, the changing factor not only affects the firm’s profit, it also implies changes in the firm’s production and pricing decisions.

31. A company is thinking about significantly expanding its production capacity. What variables would it consider in making this decision? What might be useful sources of information for estimating the potential profit impact of the expansion?

ANSWER: The most important variables are increased sales revenues and increased costs. Information on sales revenue would include current price and quantity data and the past growth rate of sales, and the impact of the firm’s advertising and promotional spending (and, of course anticipating the likely response of rival firms) on its sales. Information on costs would include the capital cost of building new facilities or expanding old ones (including borrowing costs influenced by interest rates) and annual fixed and variable costs (for equipment, labor and energy) needed to produce the greater level of output. Note that the expansion might bring the firm some reductions in average costs due to the use of new technology.

32. Mike heads a new startup firm that decides to open a number of clinics that perform laser eye surgery to correct common vision problems. He hopes that over time his company can claim a substantial share of what is estimated to be a $8 billion per year market. Briefly describe the most important factors influencing his venture’s revenues and costs. Describe the most important risks.

ANSWER: A complete answer should point out a number of obvious factors. On the demand side, the key question is the size of the total market willing and able to pay for the laser surgery (so as to dispense with glasses and contact lens). Because the procedure is not covered by insurance, demand will depend directly on the price (per eye) Mike’s company and others set for the procedure. Demand also depends upon the real and perceived risks of laser surgery. Demand issues raise a number of decision questions. How should the firm price and promote the clinics and procedures? Should it enlist elite physicians to oversee and endorse your firm’s services (as a means of differentiation)? Given current competitors and future entrants, what share of the total market can the firm reasonably expect to claim? Costs are equally important. Medical equipment and office space represent significant capital costs. Besides other operating costs, Mike’s company will pay a significant licensing fee (royalty) for each procedure to the laser’s patent holder. Of course, the ultimate average cost per patient will depend on the number of patients the firm attracts and on the scale of operation. Finally, there are significant risks – not only uncertainties on the revenue and cost sides already mentioned – but medical risks to patients and liability and regulatory risks to the company.

33. A small nation is considering upgrading its air force to incorporate new technology. It faces two main choices. The first is to acquire a fleet of the latest fighter aircraft, with the newest electronics and weapons. The cost of the acquisition (assuming that the U.S. President and Congress agree to the sale) is $45 million per plane, including a stock of spare parts that should last five years. The second choice is to buy an electronic upgrade for existing aircraft, with a complete overhaul of the airframes. The cost of such an upgrade is $8 million per plane, with about a 10% loss of fleet because of damage beyond repair and “cannibalization” to obtain the highest number of flyable planes. The upgrading of existing planes results in aircraft with about 90% of the capability of the new aircraft. Top pilots in the small country's air force are concerned that they may not be flying the best aircraft, and could face a disadvantage in combat against newer planes flown by a potential enemy. However, they acknowledge that if a numerical superiority against the enemy can be obtained, an overall victory is still likely. Their theory is that three of the upgraded planes should be able to win against one of the newer planes flown by an enemy (although the pilots expect higher losses in combat). How would an economic consultant advise the defense ministry of the small country in deciding how best to spend its available budget for air defense? What objective(s) are important for this decision? What are the pros and cons of the available options?

ANSWER: In this case, the objective is not maximum profit or operating revenue, but obtaining the best possible air force within the prescribed budget. The two main alternatives are to purchase new aircraft, or upgrade existing planes. Clearly, an important consideration is the difference in cost of the two possibilities. An upgrade is far cheaper, and results in 90% of the operational capability of the new plane. For $45 million spent on a single new plane, the country can upgrade between five and six existing aircraft. Assuming that the air force pilots are correct that three of the older, upgraded planes can defeat a single, newer plane, upgrading provides a greater effective amount of firepower in a future air conflict. However, an additional issue should be taken into account: higher pilot losses can be expected with the upgrade. The cost of lives lost can be important for a country that places a high value on human life. A sound decision should indicate at least a third possible choice, that is, to order a small number of new planes in addition to upgrading most of the old planes. The new planes could accompany the older planes on missions and stand by to combat enemy fighters. While expensive, it is cheaper than buying an entirely new fleet, and could reduce overall pilot loss.

34. In striving to make the best possible decisions, a firm’s CEO always relies on a highly analytical approach. However, the firm’s Chairman of the Board argues that in his experience, the analytical approach can only go so far. He advocates analysis as only one of several decision approaches. What is your view? Discuss and explain.
ANSWER: The virtue of the analytical approach is that it considers and analyzes the most important factors involved in a given decision. However, it is not infallible; managers may have the wrong incentives and/or pursue the wrong objectives. They might lack the necessary information to formulate a sound decision. Or they may fail to implement the decision – no matter how right it is. The key is to use the analytical approach flexibly. Different cases may require different degrees of analysis in each decision step. Certainly, the Chairman is right in insisting that there are other ways to make decisions, ranging from: company rules of thumb, invoking one’s experience, judgment and intuition, to “I’ll sleep on it”. These other means might provide useful insights and ingredients. Or to take an extreme case, sometimes, “flashes of genius” may offer decision solutions that are surprising and highly creative (and by no means irrational). For instance, a marketing plan might include radical elements constituting major changes in how a product is offered for sale. This approach is inspired, but it is also risky. It might spectacularly succeed, or just as spectacularly fail. In short, it remains the case that a sound analysis is required to articulate the logic of the decision (indeed, to convince others of its merits).
